Quark Mass Hierarchy in the Supersymmetric Composite Model

Noriaki Kitazawa*

Department of Physics, Yale University, New Haven, CT 06520, USA [†]

Abstract

A mechanism to have the quark mass hierarchy in the supersymmetric composite model is proposed. The source of the hierarchy is the kinetic-term mixing between composite quarks. Such mixing can be expected, if quarks are composite particles. A model in which the mechanism works is constructed, although it is not perfectly realistic because of some assumptions and unnaturalness.

I. INTRODUCTION

Solving the quark and lepton mass hierarchy problem is one of the most important subject in the elementary particle physics. Many mechanisms for the mass hierarchy have already been proposed. For example, in the $SU(5)$ grand unified theory the mass splitting between the bottom quark and the tau lepton can naturally be explained by the unification of their Yukawa couplings and scale dependence governed by the renormalization group equation. In the extended technicolor theory the generation of the mass hierarchy is expected as a result of the dynamics of the strong coupling chiral gauge theory.

Considering the compositeness of quarks and leptons is one of the attempt to solve the mass hierarchy problem. Especially the supersymmetric composite model is attractive, since we can naturally have tightly-bounded states whose masses are much smaller than their compositeness scales. This fact is suggested by experiments. Several interesting mechanisms for the mass hierarchy in the supersymmetric composite model have already been proposed. Having the mass hierarchy by the interplay between the chiral symmetry and the supersymmetry is proposed in Refs. [1,2]. The power of the ratio of different energy scales can give the mass hierarchy [3–6].

Almost all recent attempts to have the mass hierarchy in the supersymmetric composite model are based on the existence of hierarchical energy scales. Many models are constructed in which hierarchical Yukawa couplings are generated as the ratios of different energy scales. In these models we usually have to prepare many different energy scales and assume some non-renormalizable interactions in the Lagrangian at tree level. In this paper we propose a mechanism which is not based on the hierarchical energy scales.

The basic idea is simple. We assume the kinetic-term mixing among quarks like

$$\mathcal{L}_{kin} = \begin{pmatrix} \bar{u} & \bar{c} & \bar{t} \end{pmatrix} \begin{pmatrix} 1 & \varepsilon & 0 \\ \varepsilon & 1 & \varepsilon \\ 0 & \varepsilon & 1 \end{pmatrix} iD^\mu \gamma_\mu \begin{pmatrix} u \\ c \\ t \end{pmatrix}. \quad (1)$$

The large mixing, $\varepsilon \simeq 0.1$, can be obtained, if quarks are composite particles [7], and the texture of the mixing can be understood as a result of the dynamics of compositeness. This kinetic-term mixing is a source of the generation symmetry violation. Furthermore, we assume the interactions which are peculiar to each generation. For example, to be concrete, we consider three gauged $U(1)_{B-L}$ interactions in each generation, where B and L denote the baryon and lepton numbers, respectively. To be realistic, these interactions must be spontaneously broken, but we do not assume any hierarchical structure in the energy scales of the breaking and gauge couplings. If the mass of the top quark is generated, the masses of the charm and up quarks are generated thorough the diagrams of Fig.1. These masses are obtained as

$$m_c \simeq \frac{g^2}{16\pi^2} \varepsilon^2 m_t, \quad m_u \simeq \frac{g^2}{16\pi^2} \varepsilon^4 m_t \quad (2)$$

up to the common logarithmic correction, where g is the gauge coupling. In case of the strong coupling, $g^2/16\pi^2 \simeq 1$, we can have a good hierarchy

$$\frac{m_c}{m_t} \simeq \frac{m_u}{m_c} \simeq \varepsilon^2 \quad (3)$$

with $\varepsilon \simeq 0.07$. Here, the masses of up-type quarks at 1 GeV are $m_t \simeq 190$ GeV, $m_c \simeq 1.4$ GeV and $m_u \simeq 5$ MeV. If $U(1)_{B-L}$ gauge interactions are unique and common to each generation, the one-loop contribution gives just a correction to the kinetic-term mixing and does not generate mass eigenvalues.

In the following we construct a model in which the above situation (but not the gauged $U(1)_{B-L}$) is realized to show that the mechanism is possible. Although the model is not completely realistic because of some assumptions and unnaturalness, it is worth developing.

In the next section the one-generation (the third generation) model with dynamical supersymmetry breaking is described. The model is based on the works of Refs. [8,9]. In section III the model is extended to the three-generation model by including other two generations. The dynamics of the compositeness in each three generation are the same, namely the same structure is repeated three times. But the compositeness scales of each generation are related with each other, since confining forces are expected to be “unified” at a certain scale. The discussion on the origin of the kinetic-term mixing is also given in this section. In section IV it is explained how the quark mass hierarchy is realized in the model. Both the up-type and down-type quarks are discussed. We see that the mechanism which is briefly sketched above actually works in the model. In the last section we conclude by listing up both the satisfactory and unsatisfactory points of the model.

II. ONE-GENERATION MODEL WITH SUPERSYMMETRY BREAKING

The model of the third generation is constructed in this section. The difference of the third generation from other two generations is that it strongly couples to the supersymmetry breaking sector. The model described in this section is essentially the same of that is proposed in Ref. [9], except for the introduction of the right-handed neutrino and the difference of the notation.

A. Particle contents and Interactions

Two new gauge interactions are introduced in addition to the gauge interactions of the standard model $SU(3)_C \times SU(2)_L \times U(1)_Y$. The $SU(2)_3$ hypercolor is introduced as the confining force to have composite particles in the third generation, and the $SU(2)_S$ supercolor is introduced to realize the dynamical supersymmetry breaking. The fundamental particles of the third generation are shown in Table I, where $U(1)_{B-L}$ is a global symmetry. All the particles in Table I are singlet under the $SU(2)_S$ supercolor. In the following all fields are superfields without special notice. Note that there is no particle which belongs to the high-dimensional representation of gauge groups, and the representation is vector-like under each factor of the gauge group. In this sense, the particle contents are simple. We mention that the $U(1)_{B-L}$ symmetry can be gauged because of the inclusion of the right-handed neutrino, although we do not gauge it. The renormalizable tree-level superpotential which is general with respect to the symmetry is

$$W_H = \eta \bar{H}_3 [D_3 N_3] + \eta_{LQ} \bar{\Phi}_3 [C_3 N_3], \quad (4)$$

where square brackets denote the contraction of $SU(2)_3$ indices, $[DN] \equiv \epsilon_{\alpha\beta} D^\alpha N^\beta$, for example.

The particle contents of the supersymmetry breaking sector are shown in Table II ¹. All the particles in Table II are singlet under the standard model gauge group. Since some particles have the $SU(2)_3$ hypercolor, the supersymmetry breaking due to the $SU(2)_S$ supercolor dynamics is transmitted to the superpartners of known particles. If we neglect the $SU(2)_3$ hypercolor, the system has $SU(4)$ global symmetry ($(\tilde{Q} \ Q) \in 4$ and $(\tilde{Z} \ Z' \ Z) \in 6$). But we preserve only its subgroup $Sp(2) \sim SU(2) \times SU(2)$, and one of the $SU(2)$ subgroups of $Sp(2)$ is gauged as $SU(2)_3$. Therefore the global symmetry of this sector is $U(1)_R \times U(1)_{B-L} \times SU(2)_{global} \times Sp(2)/(SU(2)_{global} \times SU(2)_3)$. The renormalizable tree-level superpotential which is general with respect to the symmetry is

$$W_S = \lambda \text{tr}(\hat{Z}\hat{\mathcal{V}}) + 4\lambda_V Z\mathcal{V} + M_X[X_1 X_2], \quad (5)$$

where

$$\hat{\mathcal{V}} \equiv \epsilon^{ab} \begin{pmatrix} \tilde{Q} \\ Q \end{pmatrix}_a (\tilde{Q} \ Q)_b = \begin{pmatrix} 0 & \mathcal{V} + \mathcal{V}' & \tilde{\mathcal{V}}_{11} & \tilde{\mathcal{V}}_{21} \\ -(\mathcal{V} + \mathcal{V}') & 0 & \tilde{\mathcal{V}}_{12} & \tilde{\mathcal{V}}_{22} \\ -\tilde{\mathcal{V}}_{11} & -\tilde{\mathcal{V}}_{12} & 0 & \mathcal{V} - \mathcal{V}' \\ -\tilde{\mathcal{V}}_{21} & -\tilde{\mathcal{V}}_{22} & -(\mathcal{V} - \mathcal{V}') & 0 \end{pmatrix}, \quad (6)$$

$$\hat{Z} \equiv \begin{pmatrix} 0 & Z + Z' & \tilde{Z}^{11} & \tilde{Z}^{21} \\ -(Z + Z') & 0 & \tilde{Z}^{12} & \tilde{Z}^{22} \\ -\tilde{Z}^{11} & -\tilde{Z}^{12} & 0 & Z - Z' \\ -\tilde{Z}^{21} & -\tilde{Z}^{22} & -(Z - Z') & 0 \end{pmatrix}. \quad (7)$$

Here, a and b are $SU(2)_S$ indices, and the indices of fields $\tilde{\mathcal{V}}$ and $\tilde{Z}$ are explicitly written as $\tilde{\mathcal{V}}_{\alpha i}$ and $\tilde{Z}^{\alpha i}$ with the $SU(2)_3$ index α and the $SU(2)_{global}$ index i . The mass of X_1 and X_2 is introduced by hand, for simplicity, and the origin is not discussed in this paper. We simply expect that the order of the mass M_X is the energy scale of the $SU(2)_S$ dynamics. It is possible to have such mass, if we introduce additional fields [10].

We introduce the tree-level superpotential which connects above two sectors.

$$\begin{aligned} W_d = & \kappa_{\bar{H}3} \bar{H}_3 [D_3 X_1] + \kappa_{l3} l_3 [D_3 X_2] \\ & + \kappa_{\bar{\Phi}3} \bar{\Phi}_3 [C_3 X_1] + \kappa_{\bar{d}3} \bar{d}_3 [C_3 X_2] \\ & + \kappa_{\bar{\nu}3} \bar{\nu}_3 [N_3 X_1]. \end{aligned} \quad (8)$$

This renormalizable superpotential is general with respect to the symmetry. We can determine anomaly-free $U(1)_R$ charge assignment on third generation particles so that whole superpotential, Eqs.(4),(5) and (8), has charge two. Though the result is not unique, the assignment

$$\begin{array}{cccccccc} & C_3 & D_3 & N_3 & \bar{d}_3 & l_3 & \bar{\nu}_3 & \bar{\Phi}_3 & \bar{H}_3 \\ U(1)_R & 1/6 & 1/4 & 1 & 5/6 & 3/4 & 0 & 5/6 & 3/4 \end{array} \quad (9)$$

¹The explanation of the symmetry $U(1)_i$ will be given in section III

is possible, for example.

This $U(1)_R$ symmetry has to be spontaneously broken to have the masses of gauginos in the standard model. Since the resultant Nambu-Goldstone boson can couple to quarks and leptons, it may cause astrophysical and cosmological problems (the R-axion problem). Therefore, the $U(1)_R$ symmetry has to be explicitly broken by the tree-level superpotential, gauge anomaly and so on. If we believe the supergravity, the $U(1)_R$ symmetry is necessarily broken to have small cosmological constant, and the R-axion problem is solved [11].

B. Generating the One-Generation Structure

In this section we describe how the one-generation structure is realized at low energy after the confinement of the $SU(2)_3$ hypercolor.

The $SU(2)_3$ hypercolor interaction becomes strong at the confinement scale Λ_3 where all the standard model interactions are weak. It is enough to consider only the particles in Table I, since it will be shown in the next section that all $SU(2)_3$ charged particles in Table II decouple above the scale Λ_3 . It is expected that the confinement without chiral symmetry breaking occurs in the system of supersymmetric $SU(2)$ gauge theory with six doublets matter ($N_f = 3$) [12]. Namely, the massless low energy effective fields

$$\begin{aligned} M &\sim \epsilon^{\alpha\beta} \begin{pmatrix} C_3 \\ D_3 \\ N_3 \end{pmatrix}_\alpha \begin{pmatrix} C_3 & D_3 & N_3 \end{pmatrix}_\beta \\ &= \begin{pmatrix} [C_3 C_3] & [C_3 D_3] & [C_3 N_3] \\ [D_3 C_3] & [D_3 D_3] & [D_3 N_3] \\ [N_3 C_3] & [N_3 D_3] & 0 \end{pmatrix} \end{aligned} \quad (10)$$

are expected in our model. These composite particles are identified to the third generation particles as

$$M = \begin{pmatrix} \bar{u}_3 & q_3 & \Phi_3 \\ -q_3^T & \bar{e}_3 & H_3 \\ -\Phi_3^T & -H_3^T & 0 \end{pmatrix}, \quad (11)$$

where $\bar{u}_3$ and q_3 are the right-handed top quark and the left-handed weak doublet quark in the third generation, respectively, $\bar{e}_3$ is the right-handed tau lepton, H_3 is the weak doublet Higgs which can couple to up-type quarks, and Φ_3 is the leptoquark. The particle contents of the third generation with a pair of Higgs and a pair of leptoquarks are realized by these composite particles and the particles in Table I which do not have the $SU(2)_3$ hypercolor. Furthermore, it is expected that the superpotential

$$\begin{aligned} W_{dyn} &= -\alpha \text{Pf} M \\ &= \alpha (H_3 q_3 \bar{u}_3 + \Phi_3 q_3 q_3 + \Phi_3 \bar{u}_3 \bar{e}_3) \end{aligned} \quad (12)$$

is dynamically generated, where α is a dimensionless constant. The first term of this superpotential can be the Yukawa coupling for the top quark mass. The top quark naturally becomes massive, once the electroweak symmetry is spontaneously broken by the vacuum

expectation value of H_3 , since there is no global chiral symmetry which forbids the mass of the top quark in this model.

According to the naive dimensional analysis [13], the coefficient α is of the order of 4π for canonically normalized composite fields. This is too large for the top-quark Yukawa coupling (the value of $\tan\beta$ have to be very small). If we naively consider the renormalization group running of α from the compositeness scale to the low energy, it can be realized $\alpha \simeq 1$ at the low energy. But considering the renormalization group is inconsistent with the fact that the dynamically generated superpotential is a part of the exact effective action in the low energy limit. If we evaluate the quantum correction using the exact Kähler potential, the result must give only the higher order terms of the derivative expansion in the low energy effective action. In this sense the result of the renormalization group assuming the naive Kähler potential is an artifact ². The value of α is determined by the normalization of the kinetic term which is included in the unknown exact Kähler potential.

There are other ingredients to affect the value of α in the low energy limit. The direct correction to the Yukawa vertex exists by virtue of the violation of the non-renormalization theorem due to the supersymmetry breaking. The additional renormalization of the kinetic term could also exist due to the supersymmetry breaking. If it could be considered that these effects are estimated by the running of α governed by the renormalization group equation of the non-supersymmetric standard model from the supersymmetry breaking scale to the low energy, the value of α could be order of unity in the low energy limit (the supersymmetry breaking scale is determined in the next section). In this paper we simply assume that $\alpha \simeq 1$ is realized in the low energy limit.

In the following we consider the quantum correction based on the exact superpotential with naive Kähler potential to estimate the supersymmetry breaking effect. All resultant corrections disappear in the supersymmetric limit. We do not consider the quantum correction which includes the correction to the vertex of the exact superpotential by the interaction itself (for example, a diagram which includes the correction to the top-quark Yukawa vertex by the top-quark Yukawa interaction itself).

The tree-level superpotential of Eq.(4) gives the supersymmetric masses of Higgs and leptoquarks in the low energy limit as

$$W_H^{eff} = \beta\Lambda_3 \left(\eta \bar{H}_3 H_3 + \eta_{LQ} \bar{\Phi}_3 \Phi_3 \right), \quad (13)$$

where the dimensionless coefficient β is expected to be of the order of $1/4\pi$ according to the naive dimensional analysis. The first term gives so called μ -term. Therefore, $\beta\Lambda_3\eta \simeq 100$ GeV is expected. The mass of the leptoquarks must be large enough not to contradict with the direct search. And if they couple to the particles in the first generation, the mass must be very heavy or the coupling must be very small to avoid rapid proton decay.

C. Dynamical Supersymmetry Breaking

In this section the dynamical supersymmetry breaking in the system of Table II with the tree-level superpotential of Eq.(5) and its transmission to the superpartners of known

²In general, the dynamically generated superpotential is non-renormalizable.

particles are explained.

We consider that the confinement scale of the $SU(2)_S$ supercolor, Λ_S , is larger than that of the $SU(2)_3$ hypercolor, Λ_3 . Therefore, the $SU(2)_3$ hypercolor interaction is weak at the scale Λ_S . Then, the system of Table II is simply considered as the $SU(2)_S$ gauge theory with four doublets matter which interact with singlet fields through the superpotential of Eq.(5). The confinement at the scale Λ_S and the gauge singlet low energy effective field

$$\hat{V} \sim \hat{\mathcal{V}} \quad (14)$$

are expected (see Eq.(6)). Furthermore, the superpotential

$$W_{dyn}^S = A \left(\text{Pf} \hat{V} - (\beta \Lambda_S)^2 \right) \quad (15)$$

is expected to be generated dynamically, where A is a Lagrange multiplier chiral superfield and $\beta \simeq 1/4\pi$ according to the naive dimensional analysis. This superpotential gives the following constraint between the components of the matrix $\hat{V}$.

$$V^2 = (\beta \Lambda_S)^2 + V'^2 + [\tilde{V}_1 \tilde{V}_2]. \quad (16)$$

Namely, V is not the independent field.

The tree-level superpotential of Eq.(5) gives the following low energy effective superpotential.

$$\begin{aligned} W_S^{eff} &= \lambda \beta \Lambda_S \text{tr}(\hat{Z} \hat{V}) + 4\lambda_V \beta \Lambda_S ZV + M_X [X_1 X_2] \\ &= -4(\lambda - \lambda_V) \beta \Lambda_S ZV - 4\lambda \beta \Lambda_S \left(Z' V' + \frac{1}{2} \tilde{Z}^{\alpha i} \tilde{V}_{\alpha i} \right) + M_X [X_1 X_2]. \end{aligned} \quad (17)$$

By substituting the constraint of Eq.(16) to the above equation, we have

$$\begin{aligned} W_S^{eff} &= -4(\lambda - \lambda_V) Z \left\{ (\beta \Lambda_S)^2 + \frac{1}{2} V'^2 + \frac{1}{2} [\tilde{V}_1 \tilde{V}_2] + \mathcal{O}((\beta \Lambda_S)^{-2}) \right\} \\ &\quad - 4\lambda \beta \Lambda_S \left(Z' V' + \frac{1}{2} \tilde{Z}^{\alpha i} \tilde{V}_{\alpha i} \right) + M_X [X_1 X_2]. \end{aligned} \quad (18)$$

This shows that the system becomes the O'Raifeartaigh model at the low energy. Namely, the auxiliary component of Z gets vacuum expectation value of

$$\langle F_Z^\dagger \rangle = - \left\langle \frac{\partial W_S^{eff}}{\partial Z} \right\rangle = 4(\lambda - \lambda_S) (\beta \Lambda_S)^2, \quad (19)$$

and the supersymmetry is spontaneously broken. The supersymmetry is dynamically broken due to the modification of the moduli space by the quantum effect [14,15].

The mass spectrum of this system at the low energy is briefly described as follows. The second term of Eq.(18) means that the pairs of Z' and V' and $\tilde{Z}$ and $\tilde{V}$ have supersymmetric masses of $4\lambda \beta \Lambda_S$ and $m' \equiv 2\lambda \beta \Lambda_S$, respectively. The supersymmetric mass of X_1 and X_2 , M_X , is assumed to be of the order of m' as discussed in section II A. Since the auxiliary component of Z has vacuum expectation value, the scalar components of V' and $\tilde{V}$ have soft supersymmetry breaking masses of $(4(\lambda - \lambda_S) \beta \Lambda_S)^2$ and $F \equiv 8((\lambda - \lambda_S) \beta \Lambda_S)^2$, respectively. Note that $\tilde{V}$ couples to $SU(2)_3$ hypercolor. The supersymmetry breaking is transmitted by

this particle to known particles through the $SU(2)_3$ hypercolor interaction, and the masses of squarks, sleptons and gauginos are generated. The fermion component of Z is the Nambu-Goldstone fermion associated with the spontaneous supersymmetry breaking.

The scalar component of Z is massless, since it parameterizes the pseudo-flat direction which is common in the O’Raifeartaigh model at tree level. If the pseudo-flat direction is lifted up by the effect of the non-trivial Kähler potential, it becomes massive. If the resultant squared mass is negative, it obtains vacuum expectation value and $U(1)_R$ symmetry is spontaneously broken. A mechanism which is proposed in Ref. [16] is a candidate of the dynamics to have such vacuum expectation value. In that mechanism the scale of the vacuum expectation value can naturally be much larger than that of the supersymmetry breaking. But it can not be directly applied to our model. In this paper we simply assume that $m \equiv 2(\lambda - \lambda_V)\langle A_Z \rangle \neq 0$ and $m \gg \sqrt{F}$, where A_Z is the scalar component of Z . Therefore, the fields V' and $\tilde{V}$ have supersymmetric masses, $2m$ and m , respectively, which break $U(1)_R$ symmetry.

The detailed descriptions on the mass spectrum of the $SU(2)_3$ hypercolored particles, $\tilde{Z}$ and $\tilde{V}$, and the transmission of the supersymmetry breaking to known particles are given in Ref. [9]. In the following we give only a brief sketch of the transmission of the supersymmetry breaking to the superpartners of known particles.

The gaugino of the $SU(2)_3$ hypercolor becomes massive due to the one-loop diagram which includes the propagators of $\tilde{V}$.

$$m_\lambda^{SU(2)_3} \simeq \frac{\alpha_H F}{8\pi m}, \quad (20)$$

where α_H is the gauge coupling of the $SU(2)_3$ hypercolor interaction. The gauginos of standard model gauge groups become massive due to the two-loop diagram which includes the propagator of the $SU(2)_3$ gaugino and “preons” C_3 and D_3 in Table I.

$$m_{\lambda_N} \simeq \frac{3\alpha_N}{8\pi} \left(\frac{\alpha_H}{4\pi} \right)^2 \frac{F}{m} \ln \left(\frac{m}{\Lambda_3} \right), \quad (21)$$

where $N = 1, 2$ and 3 correspond to the standard model interactions $U(1)_Y$, $SU(2)_L$ and $SU(3)_C$, respectively. The scalar components of “preons” C_3 , D_3 and N_3 in Table I become massive due to the two-loop diagrams which include the propagators of $\tilde{V}$ and the $SU(2)_3$ gauge boson and gaugino.

$$\tilde{m}_P^2 \simeq \frac{3}{2} \left(\frac{\alpha_H}{4\pi} \right)^2 \left(\frac{F}{m} \right)^2. \quad (22)$$

Note that these results are based on the perturbation on the gauge coupling of the $SU(2)_3$ hypercolor interaction. Therefore, we can not use these results at low energy, since the hypercolor interaction becomes strong. We assume that putting $\alpha_H/4\pi \simeq 1$ in the above formulae gives at least correct order of magnitude of these quantities. Namely, we use

$$m_{\lambda_N} \simeq \frac{3\alpha_N F}{8\pi m} \ln \left(\frac{m}{\Lambda_3} \right), \quad \tilde{m}_P^2 \simeq \frac{3}{2} \left(\frac{F}{m} \right)^2 \quad (23)$$

in the following. In the next section we see that the condition $m_\lambda^{SU(2)_3}, \tilde{m}_P \ll \Lambda_3$ is satisfied, which is necessary to the argument in the last section.

The scalar components of the composite fields which belong to M of Eq.(11) are expected to have masses of the order of $\tilde{m}_P$. The scalar components of the elementary particles becomes massive due to the one-loop diagram which includes massive gaugino propagator. For example, the right-handed scalar bottom quark obtains the mass of

$$m_{\tilde{b}_R}^2 \simeq \frac{4\alpha_3}{3\pi} m_{\lambda_3}^2 \ln \left(\frac{\Lambda_3^2}{m_{\lambda_3}^2} \right). \quad (24)$$

In the next section we introduce the first and second generations. Since the particles in these generations do not strongly couple to the supersymmetry breaking sector, all masses of squarks and sleptons in these generations are generated in the same way of the mass of the right-handed scalar bottom quark. Therefore, the soft supersymmetry breaking masses of these two generations are highly degenerate in flavor, which is a good feature for the flavor-changing neutral current problem in the supersymmetric theory [17].

D. Electroweak Symmetry Breaking

In this model the electroweak symmetry breaking is triggered by the radiative correction due to the strong top-quark Yukawa coupling [18]. In the low energy limit we have the Higgs potential as

$$V_{tree} = \frac{1}{2} (\mu^2 + \tilde{m}_{\bar{H}}^2) \bar{h}^2 + \frac{1}{2} (\mu^2 + \tilde{m}_H^2) h^2 + B\bar{h}h + \frac{g_1^2 + g_2^2}{32} (\bar{h}^2 - h^2)^2, \quad (25)$$

where $\bar{h}/\sqrt{2}$ and $h/\sqrt{2}$ are the electrically neutral scalar components of $\bar{H}$ and H , respectively, $\mu = \beta\Lambda_3\eta$ is the supersymmetric mass, $\tilde{m}_{\bar{H}}$, $\tilde{m}_H$ and B are soft supersymmetry breaking masses, and g_1 and g_2 are the gauge couplings of $U(1)_Y$ and $SU(2)_L$ gauge interactions, respectively. Since H is composite, $\tilde{m}_H^2 \simeq \tilde{m}_P^2$. Other supersymmetry breaking masses are generated as the quantum correction [9].

$$\tilde{m}_{\bar{H}}^2 \simeq \frac{\alpha_1}{8\pi} \left\{ \mu_{LQ}^2 \ln \left(1 + \frac{\tilde{m}_P^2}{\mu_{LQ}^2} \right) - \mu^2 \ln \left(1 + \frac{\tilde{m}_P^2}{\mu^2} \right) + \tilde{m}_P^2 \ln \left(\frac{\mu_{LQ}^2 + \tilde{m}_P^2}{\mu^2 + \tilde{m}_P^2} \right) \right\}, \quad (26)$$

$$B = \frac{3\alpha_2}{4\pi} \frac{m_{\lambda_2}\mu}{m_{\lambda_2}^2 - \mu^2} \left\{ m_{\lambda_2}^2 \ln \left(\frac{\Lambda_3^2}{m_{\lambda_2}^2} \right) - \mu^2 \ln \left(\frac{\Lambda_3^2}{\mu^2} \right) \right\} \\ + \frac{\alpha_1}{2\pi} \frac{m_{\lambda_1}\mu}{m_{\lambda_1}^2 - \mu^2} \left\{ m_{\lambda_1}^2 \ln \left(\frac{\Lambda_3^2}{m_{\lambda_1}^2} \right) - \mu^2 \ln \left(\frac{\Lambda_3^2}{\mu^2} \right) \right\}, \quad (27)$$

where $\mu_{LQ} = \beta\Lambda_3\eta_{LQ}$ is the supersymmetric mass of the leptoquark. Both quantities vanish in the supersymmetric limit ($\tilde{m}_P^2, m_{\lambda_{1,2}} \rightarrow 0$). The quantity $\tilde{m}_{\bar{H}}$ also vanishes, if $\mu_{LQ} = \mu$. The electroweak symmetry breaking does not occur in this tree-level potential, since the relation $B^2 < (\mu^2 + \tilde{m}_{\bar{H}}^2)(\mu^2 + \tilde{m}_H^2)$ is satisfied (note that $\tilde{m}_{\bar{H}}^2 > 0$ and $(B/\mu)^2 < \tilde{m}_H^2$).

The one-loop diagrams of the top quark and the scalar top quark give the contribution of

$$V_{1-loop} = \frac{3}{8\pi^2} \int_0^{\Lambda_3^2} dk^2 k^2 \left\{ \ln \left(1 + \frac{g_t^2 h^2 / 2}{k^2 + m_t^2} \right) - \ln \left(1 + \frac{g_t^2 h^2 / 2}{k^2} \right) \right\}, \quad (28)$$

where g_t is the Yukawa coupling of the top quark at the low energy, and $m_t^2 \simeq \tilde{m}_P^2$ is the mass of the scalar top quark. This contribution vanishes in the supersymmetric limit ($m_t^2 \simeq \tilde{m}_P^2 \rightarrow 0$).

The stationary conditions of whole potential with respect to the fields $\bar{h}$ and h give the following conditions.

$$\mu^2 + \tilde{m}_H^2 + B \tan \beta + \frac{1}{2} m_Z^2 \cos 2\beta = 0, \quad (29)$$

$$\begin{aligned} & \mu^2 + \tilde{m}_H^2 + B \cot \beta - \frac{1}{2} m_Z^2 \cos 2\beta \\ & - \frac{3}{4\pi^2} \frac{m_t^2}{v^2 \sin^2 \beta} \left\{ (m_t^2 + m_t^2) \ln \frac{m_t^2 + m_t^2 + \Lambda_3^2}{m_t^2 + m_t^2} - m_t^2 \ln \frac{m_t^2 + \Lambda_3^2}{m_t^2} \right\} = 0, \end{aligned} \quad (30)$$

where valuables h and $\bar{h}$ are replaced by v and β following $h = v \sin \beta$ and $\bar{h} = v \cos \beta$, and the constraints $(g_1^2 + g_2^2)v^2/4 = m_Z^2$ and $g_t^2 h^2/2 = m_t^2$ are applied. The first condition determines $\tan \beta$, and the second condition determines the compositeness scale Λ_3 .

We estimate the numerical values of $\tan \beta$ and Λ_3 . The soft supersymmetry breaking mass of preons, $\tilde{m}_P^2$, have to be large enough for heavy gauginos (see Eq.(23)). We set $\tilde{m}_P^2 = (10\text{TeV})^2$ and $m/\Lambda_3 \simeq 10^3$, then

$$m_{\lambda_1} \simeq 70 \text{ GeV}, \quad (31)$$

$$m_{\lambda_2} \simeq 200 \text{ GeV}, \quad (32)$$

$$m_{\lambda_3} \simeq 700 \text{ GeV}. \quad (33)$$

Once gaugino masses are determined, the value of B can be determined up to logarithm giving the value of μ . We set $\mu = -50 \text{ GeV}$ and assume $\ln(\Lambda_3/m_{\lambda_{1,2}}) \simeq \ln(\Lambda_3/\mu) \simeq 14$, (this assumption will be consistently confirmed by the result), then

$$B \simeq -2000 (\text{GeV})^2. \quad (34)$$

Moreover, we set $\mu_{LQ} = 1 \text{ TeV}$, then

$$\tilde{m}_H^2 \simeq (50 \text{ GeV})^2. \quad (35)$$

By putting all these values to Eqs. (29) and (30), we have

$$\tan \beta \simeq 1.5, \quad (36)$$

$$\Lambda_3 \simeq 10^8 \text{ GeV}. \quad (37)$$

The value of Λ_3 is consistent with the above assumption on the logarithmic factor, since $\ln(\Lambda_3/100\text{GeV}) \simeq 14$. We can obtain the value of the top-quark Yukawa coupling from the value of $\tan \beta$ as

$$g_t = \sqrt{\frac{2m_t^2}{v^2 \sin^2 \beta}} \simeq 1.2 \quad (38)$$

which is consistent with the expectation that the coupling is of the order of unity. The obtained value of Λ_3 means that the compositeness scale of the third generation is very large.

III. THREE-GENERATION MODEL

In this section we construct the three-generation model by introducing other two generations to the model described in section II. We consider that the first and second generations have the same compositeness structure of the third generation. The particle contents are shown in Table III. Here, we have introduced two new hypercolor gauge interactions, $SU(2)_1$ and $SU(2)_2$, whose confinement scales are Λ_1 and Λ_2 , respectively. It is expected that all known particle contents of three generations with a pair of Higgs and a pair of leptoquarks in each generation are realized below the confinement scales in the same way of which is described in section II B. The dynamically generated superpotential at the low energy is expected as

$$W_{dyn} = \alpha (H_i q_i \bar{u}_i + \Phi_i q_i q_i + \Phi_i \bar{u}_i \bar{e}_i), \quad (39)$$

where $i = 1, 2$ and 3 denotes the generation and $\alpha \simeq 4\pi$ (see Eq.(12)). Note that there is no generation mixing in these Yukawa couplings, since the confining dynamics are different in each generation.

We have also introduced three global $U(1)$ symmetries in each generation (see also Table II). This $U(1)_i$ symmetry is a kind of the generation symmetry which forbids the mixing among generations. Note that it distinguishes the preons N_i which are singlet under the standard model gauge group from the preons C_i and D_i which have the quantum number of the standard model gauge group. This symmetry is explicitly broken only by the $SU(2)_i$ hypercolor gauge anomaly, and the breaking effect appears only through the dynamically generated superpotential of Eq.(39) [19].

The tree-level superpotential of Eq.(4) is generalized as

$$W_H = \eta^i \bar{H}_i [D_i N_i] + \eta_{LQ}^i \bar{\Phi}_i [C_i N_i]. \quad (40)$$

In the low energy limit this superpotential gives mass terms of Higgs and leptoquarks.

$$W_H^{eff} = \beta \left(\eta^i \Lambda_i \bar{H}_i H_i + \eta_{LQ}^i \Lambda_i \bar{\Phi}_i \Phi_i \right), \quad (41)$$

where $\beta \simeq 1/4\pi$.

The leptoquark in the first generation, Φ_1 , must be very heavy, otherwise proton rapidly decays by its tree-level exchange through the baryon number violating interaction in Eq.(39). It must be heavier than at least 10^{17} GeV so that the life time of proton is longer than 10^{32} years [20]. Therefore, we set the confinement scale of the first generation $\Lambda_1 \simeq 10^{18}$ GeV with $\eta_{LQ}^1 \simeq 1$. On the other hand, the confinement scale of the third generation has already determined in section II C as $\Lambda_3 \simeq 10^8$ GeV in accord with the radiative electroweak symmetry breaking. This hierarchy among compositeness scales can be understood as follows.

We consider that the gauge couplings of three $SU(2)_i$ hypercolors coincide at very high energy (unification, for example). Since the third generation strongly couples to the supersymmetry breaking sector, or the supersymmetry breaking sector includes $SU(2)_3$ hypercolored particles, the running of the $SU(2)_3$ gauge coupling is slower than the others, and the hierarchy, $\Lambda_3 \ll \Lambda_1 \simeq \Lambda_2$, can be realized. In fact, the one-loop β -function of the $SU(2)_3$ hypercolor gauge coupling vanishes at the high energy, since there are 12 doublets ($N_f = 6$).

We can understand from the superpotential of Eq.(18) how the $SU(2)_3$ hypercolored particles in the supersymmetry breaking sector decouple. At the scale m the effective field $\tilde{V}$ decouples, where m is the supersymmetric mass of $\tilde{V}$ and we are assuming $m/\Lambda_3 \simeq 10^3$. Furthermore, at the scale m' the field $\tilde{Z}$ decouples. Since we are assuming $M_X \simeq m'$, the field X also decouples at this scale. Therefore, we can imagine the running of hypercolor gauge couplings as Fig. 2. The “unification scale” Λ_U and the value of the “unified gauge coupling” α_U are obtained as follows using the one-loop renormalization group equations.

$$\Lambda_U \simeq 5 \times 10^{19} \text{ GeV}, \quad (42)$$

$$\alpha_U \simeq 0.35. \quad (43)$$

The “unification scale” is about the Planck scale, and the “unified gauge coupling” is rather strong.

Although we do not specify the physics at the energy scale Λ_U , we assume that the following kinetic-term mixing is generated.

$$K_{eff} = \begin{pmatrix} \bar{u}_1^\dagger & \bar{u}_2^\dagger & \bar{u}_3^\dagger \end{pmatrix} \begin{pmatrix} 1 & \varepsilon & 0 \\ \varepsilon & 1 & \varepsilon \\ 0 & \varepsilon & 1 \end{pmatrix} \begin{pmatrix} \bar{u}_1 \\ \bar{u}_2 \\ \bar{u}_3 \end{pmatrix} + \begin{pmatrix} q_1^\dagger & q_2^\dagger & q_3^\dagger \end{pmatrix} \begin{pmatrix} 1 & \varepsilon & 0 \\ \varepsilon & 1 & \varepsilon \\ 0 & \varepsilon & 1 \end{pmatrix} \begin{pmatrix} q_1 \\ q_2 \\ q_3 \end{pmatrix}, \quad (44)$$

where we neglect gauge fields, for simplicity. It is not unnatural that the composite particles, $\bar{u}_i$ and q_i , have kinetic-term mixing at the tree level of the low energy effective Lagrangian. The origin of the kinetic-term mixing could be considered as follows. It can be expected that the physics at the scale Λ_U equally treats each generation, and generates higher dimensional interaction in the Kähler potential like

$$K_{\Lambda_U} = \frac{1}{\Lambda_U^2} \begin{pmatrix} [C_1 C_1]^\dagger & [C_2 C_2]^\dagger & [C_3 C_3]^\dagger \end{pmatrix} \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} [C_1 C_1] \\ [C_2 C_2] \\ [C_3 C_3] \end{pmatrix}. \quad (45)$$

In the low energy limit this interaction gives kinetic-term mixing

$$K_{\Lambda_U}^{eff} = \begin{pmatrix} \bar{u}_1^\dagger & \bar{u}_2^\dagger & \bar{u}_3^\dagger \end{pmatrix} \frac{1}{\Lambda_U^2} \begin{pmatrix} \Lambda^2 & \Lambda^2 & \Lambda\Lambda_3 \\ \Lambda^2 & \Lambda^2 & \Lambda\Lambda_3 \\ \Lambda_3\Lambda & \Lambda_3\Lambda & \Lambda_3^2 \end{pmatrix} \begin{pmatrix} \bar{u}_1 \\ \bar{u}_2 \\ \bar{u}_3 \end{pmatrix}, \quad (46)$$

where $\Lambda \equiv \Lambda_1 = \Lambda_2$. Since $\Lambda^2/\Lambda_U^2 \simeq 0.01$ and $\Lambda\Lambda_3/\Lambda_U^2 \simeq 10^{-12}$, the kinetic-term mixing between the first and the second generations is relatively large, and the mixings between the third generation and the others are very small. To have the structure of Eq.(44), we have to include some new mechanisms to generate the large mixing between the second and the third generations. An example of such mechanism has proposed in Ref. [7]. Note that the kinetic-term mixings among leptoquarks and among Higgs fields are forbidden by the $U(1)_i$ symmetry.

We can not avoid to consider the hierarchical structure in the couplings η^i and η_{LQ}^i . The couplings η_{LQ}^i must have the values of

$$\eta_{LQ}^1 \simeq \eta_{LQ}^2 \simeq 1, \quad \eta_{LQ}^3 \simeq 10^{-4}. \quad (47)$$

The small value of η_{LQ}^3 is needed to have an appropriate value of the soft supersymmetry breaking mass $\tilde{m}_H^2$ for the radiative electroweak symmetry breaking (see Eq.(26)). At present the couplings η^i are determined as

$$\eta^1 \simeq \eta^2 \simeq \bar{\eta}, \quad \eta^3 \simeq 10^{-5}. \quad (48)$$

The value of $\bar{\eta}$ will be determined in the next section.

The superpotential of Eq.(8) which connects between the supersymmetry breaking sector and remainder is generalized as follows due to the introduction of the first and second generations.

$$\begin{aligned} W_d = & \kappa_{\bar{H}i} \bar{H}_i [D_3 X_1] + \kappa_{li} l_i [D_3 X_2] \\ & + \kappa_{\bar{\Phi}i} \bar{\Phi}_i [C_3 X_1] + \kappa_{\bar{d}i} \bar{d}_i [C_3 X_2] \\ & + \kappa_{\bar{\nu}i} \bar{\nu}_i [N_3 X_1]. \end{aligned} \quad (49)$$

Only the hypercolor-singlet fields in the fundamental particles of the first and second generations can be included. Here, the third generation and remainder are not equally treated.

IV. GENERATION OF THE QUARK MASS HIERARCHY

A. Up-type Quarks

We have already shown in section IID that the electroweak symmetry breaking is triggered by the radiatively-induced vacuum expectation values of the Higgs fields in the third generation, H_3 and $\bar{H}_3$. The top quark becomes massive through the Yukawa coupling which is generated dynamically. On the other hand, the Higgs fields in the first and second generations can not have vacuum expectation values, if their supersymmetric masses, or the coupling $\bar{\eta}$ in Eq.(48), is large enough. Therefore, the up and charm quarks remain massless, even if there are strong Yukawa couplings with the Higgs fields in each generation. In the following we describe that the idea which is briefly introduced in section I is realized in this model.

Two ingredients are needed to have the quark mass hierarchy. One is the kinetic-term mixing among quarks, and the other is the strong interactions which are peculiar to each generation. The kinetic-term mixing has already introduced in Eq.(44). The required strong interactions are dynamically-generated Yukawa interactions of Eq.(39). The up-type quarks in the first and second generations interact only with the Higgs field H_1 and H_2 through the Yukawa interactions, respectively. Then, we have the hierarchical masses of the charm and up quarks through the diagrams of Fig. 3. These tadpole diagrams can also be understood as the effect of the Higgs particle mixing which is induced by the kinetic-term mixing. Since there is no direct transition from the up quark to the top quark, the mass of the up quark is suppressed by the factor ε^2 in comparison with the charm quark mass. The evaluation of the diagram gives

$$m_c \simeq \frac{6\alpha^2}{16\pi^2} \varepsilon^2 m_t \frac{\tilde{m}_P^2}{M_H^2}, \quad m_u \simeq \varepsilon^2 m_c, \quad (50)$$

where $\alpha \simeq 4\pi$ and $M_H \equiv \beta\Lambda\bar{\eta}$ with $\Lambda \equiv \Lambda_1 = \Lambda_2$ is the common mass of the Higgs fields H_1 and H_2 . Since the quadratic divergence of these diagrams is canceled out in the supersymmetric limit, we take the mass of the scalar top quark $m_t^2 \simeq \tilde{m}_P^2$ as the ultraviolet cutoff.

If the mass M_H is of the order of $\tilde{m}_P$, namely $M_H \simeq 10$ TeV, we have a good hierarchy

$$\frac{m_c}{m_t} \simeq \frac{m_u}{m_c} \simeq \varepsilon^2 \quad (51)$$

with $\varepsilon \simeq 0.07$, since

$$\frac{m_c}{m_t} \simeq 7 \times 10^{-3}, \quad \frac{m_u}{m_c} \simeq 4 \times 10^{-3}, \quad (52)$$

where $m_t \simeq 190$ GeV, $m_c \simeq 1.4$ GeV and $m_u \simeq 5$ MeV at the energy scale 1 GeV.

Taking $M_H \simeq 10$ TeV means a huge hierarchy in the couplings η^i of Eq.(48). Namely, $\bar{\eta}$ must be of the order of 10^{-13} because $M_H = \beta\Lambda\bar{\eta}$ and $\Lambda \simeq 10^{18}$ GeV. Moreover, we have to note that this value of M_H is marginal not to have the vacuum expectation values of H_1 and H_2 due to the radiative correction by strong Yukawa couplings.

B. Down-type Quarks

The generation of the mass hierarchy among down-type quarks is not simple in comparison with that of up-type quarks. At first, we show that all right-handed down-type quarks can couple to Higgs fields $\bar{H}_i$ in the low energy limit.

The fields X_1 and X_2 which are included in the tree-level superpotential of Eq.(49) have the supersymmetric mass of $M_X \simeq m' \simeq 10^9$ GeV. Therefore, these fields decouple before the confinement of the third generation. Since soft supersymmetry breaking masses are negligible at this high energy scale ($\tilde{m}_P \simeq m_{\lambda}^{SU(2)_3} \simeq 10^4$ GeV), we can integrate out these fields by using the conditions of $\partial(W_d + W_S^{eff})/\partial X_{1,2} = 0$, where W_S^{eff} includes the mass term of these fields (see Eq.(18)). The resultant effective superpotential is

$$W'_d = -\frac{1}{M_X} \left\{ \begin{aligned} &\kappa_{\bar{H}_i\kappa_{lj}}\bar{H}_i [D_3D_3] l_j + \kappa_{\bar{H}_i\kappa_{\bar{d}j}}\bar{H}_i [D_3C_3] \bar{d}_j \\ &+ \kappa_{\bar{\Phi}_i\kappa_{lj}}\bar{\Phi}_i [C_3D_3] l_j + \kappa_{\bar{\Phi}_i\kappa_{\bar{d}j}}\bar{\Phi}_i [C_3C_3] \bar{d}_j \\ &+ \kappa_{\bar{\nu}_i\kappa_{lj}}\bar{\nu}_i [N_3D_3] l_j + \kappa_{\bar{\nu}_i\kappa_{\bar{d}j}}\bar{\nu}_i [N_3C_3] \bar{d}_j \end{aligned} \right\}. \quad (53)$$

In the low energy limit (below the confinement scale Λ_3) this superpotential gives the Yukawa couplings of

$$W_d^{eff} = -\frac{\beta\Lambda_3}{M_X} \left\{ \begin{aligned} &\kappa_{\bar{H}_i\kappa_{lj}}\bar{H}_i\bar{e}_3l_j - \kappa_{\bar{H}_i\kappa_{\bar{d}j}}\bar{H}_iq_3\bar{d}_j \\ &+ \kappa_{\bar{\Phi}_i\kappa_{lj}}\bar{\Phi}_iq_3l_j + \kappa_{\bar{\Phi}_i\kappa_{\bar{d}j}}\bar{\Phi}_i\bar{u}_3\bar{d}_j \\ &- \kappa_{\bar{\nu}_i\kappa_{lj}}\bar{\nu}_iH_3l_j - \kappa_{\bar{\nu}_i\kappa_{\bar{d}j}}\bar{\nu}_i\Phi_3\bar{d}_j \end{aligned} \right\}, \quad (54)$$

where $\beta \simeq 1/4\pi$. The second term gives the bottom quark mass and the mass mixings between left-handed bottom quark and the right-handed down and strange quarks through the vacuum expectation value of $\bar{H}_3$.

Here, we give some comments on the generation of the lepton mass. The first and fifth terms of Eq.(54) give the mass matrices of charged leptons and neutrinos, respectively. But there is no physics which explains the hierarchy of these masses, except for that the tau lepton can be naturally heavier than the other charged leptons. One interesting thing is a relation between the smallness of neutrino masses and the long life time of proton. The coupling of the last term of Eq.(54) must be very small not to have rapid proton decay. If we take the value of $\kappa_{\bar{\nu}i}$ very small, the masses of neutrinos become very small simultaneously. The value of the coupling $\kappa_{\bar{\Phi}i}$ also must be very small not to have rapid proton decay.

In the following we only consider the second term of Eq.(54) to discuss the masses of down-type quarks. Due to the vacuum expectation value of the scalar component of the Higgs field $\bar{H}_3$, we obtain the following mass matrix for down-type quarks.

$$\mathcal{L}_d^{mass} = - \begin{pmatrix} \bar{d}_R & \bar{s}_R & \bar{b}_R \end{pmatrix} M_d^{tree} \begin{pmatrix} d_L \\ s_L \\ b_L \end{pmatrix} + \text{h.c.}, \quad (55)$$

$$M_d^{tree} = \frac{\beta\Lambda_3}{M_X} \frac{v}{\sqrt{2}} \cos\beta \kappa_{\bar{H}3} \begin{pmatrix} 0 & 0 & \kappa_{\bar{d}1} \\ 0 & 0 & \kappa_{\bar{d}2} \\ 0 & 0 & \kappa_{\bar{d}3} \end{pmatrix}, \quad (56)$$

where $d_{L,R}$, $s_{L,R}$ and $b_{L,R}$ are the left-handed and right-handed down, strange and bottom fermion fields, respectively (The coefficient β is different from the β in $\cos\beta$). The unique non-zero eigenvalue of this mass matrix is

$$m_b = \frac{\beta\Lambda_3}{M_X} \frac{v}{\sqrt{2}} \cos\beta \kappa_{\bar{H}3} \kappa_{\bar{d}3}, \quad (57)$$

and it is the bottom quark mass. The down and strange quarks remain massless at this level. The value $m_b \simeq 5.7$ GeV at 1 GeV gives $\kappa_{\bar{H}3} \kappa_{\bar{d}3} \simeq 7.3$. This means that the couplings κ are supposed to be of the order of unity, in general. The value of the bottom-quark Yukawa coupling is

$$g_b = \frac{\beta\Lambda_3}{M_X} \kappa_{\bar{H}3} \kappa_{\bar{d}3} \simeq 6 \times 10^{-2}. \quad (58)$$

The second term of the superpotential of Eq.(54) gives also the Yukawa couplings between two heavy Higgs, the left-handed quarks in the third generation and all right-handed down-type quarks. The interplay between these Yukawa couplings and dynamically-generated Yukawa couplings gives the masses of the strange and down quarks through the diagrams in Fig. 4. In each diagram right couplings are dynamically-generated Yukawa couplings $\alpha \simeq 4\pi$, and left couplings are Yukawa couplings from Eq.(54),

$$g_s = \frac{\beta\Lambda_3}{M_X} \kappa_{\bar{H}2} \kappa_{\bar{d}2}, \quad g_d = \frac{\beta\Lambda_3}{M_X} \kappa_{\bar{H}1} \kappa_{\bar{d}1}. \quad (59)$$

The soft supersymmetry breaking mass B_H is obtained as

$$\begin{aligned}
B_H &= \frac{3\alpha_2}{4\pi} \frac{m_{\lambda_2} M_H}{m_{\lambda_2}^2 - M_H^2} \left\{ m_{\lambda_2}^2 \ln \left(\frac{\Lambda^2}{m_{\lambda_2}^2} \right) - M_H^2 \ln \left(\frac{\Lambda^2}{M_H^2} \right) \right\} \\
&\quad + \frac{\alpha_1}{2\pi} \frac{m_{\lambda_1} M_H}{m_{\lambda_1}^2 - M_H^2} \left\{ m_{\lambda_1}^2 \ln \left(\frac{\Lambda^2}{m_{\lambda_1}^2} \right) - M_H^2 \ln \left(\frac{\Lambda^2}{M_H^2} \right) \right\} \\
&\simeq \frac{3\alpha_2}{2\pi} m_{\lambda_2} M_H \ln \left(\frac{\Lambda}{M_H} \right) + \frac{\alpha_1}{\pi} m_{\lambda_1} M_H \ln \left(\frac{\Lambda}{M_H} \right) \simeq (1 \text{ TeV})^2
\end{aligned} \tag{60}$$

in exactly the same way of Eq.(27).

The diagrams of Fig. 4 gives

$$m_s \simeq \frac{g_s \alpha}{16\pi^2} \varepsilon m_t \frac{B_H}{M_H^2}, \tag{61}$$

$$m_d \simeq \frac{g_d \alpha}{16\pi^2} \varepsilon^2 m_t \frac{B_H}{M_H^2}. \tag{62}$$

If we naturally consider that $g_s \simeq g_d$, we have

$$\frac{m_d}{m_s} \simeq \varepsilon \simeq 0.07. \tag{63}$$

Since the up quark can not directly transit to the top quark, the mass of the down quark is suppressed by the factor of ε than that of the strange quark. This is a good result, since $m_d \simeq 10 \text{ MeV}$ and $m_s \simeq 200 \text{ MeV}$ at 1 GeV .

The strong coupling $g_s \simeq 20$ is required to have the realistic value of the strange quark mass. This value is much larger than g_b , and it corresponds to $\kappa_{\bar{H}2}\kappa_{\bar{d}2} = g_s M_X / \beta \Lambda_3 \simeq 3 \times 10^3$. We have to assume the hierarchy of the order of

$$\sqrt{\frac{\kappa_{\bar{H}2}\kappa_{\bar{d}2}}{\kappa_{\bar{H}3}\kappa_{\bar{d}3}}} \sim 10 \tag{64}$$

between the couplings in the tree level superpotential.

The origin of the bottom quark mass is different from the one of the down and strange quarks in this model. The bottom quark mass is generated at the tree level of the low energy effective Lagrangian, and the others are generated at the one-loop level. Therefore, it is natural that the bottom quark is heavier than that of the others, but the suppression due to the loop factor is too strong. The hierarchy between the masses of the down and strange quarks is naturally explained by the structure of the kinetic-term mixing.

V. CONCLUSION

We have proposed a mechanism to have the quark mass hierarchy in the supersymmetric composite model. The two important ingredients of the mechanism are the kinetic-term mixing between the composite quarks, which can be naturally generated due to the compositeness, and the strong interactions which are peculiar to each generation. We have constructed a model in which the mechanism works. Since we need some assumptions on

the dynamics and the hierarchical structure between the couplings in the tree-level superpotential, the model is not completely realistic. The another mechanism for the quark mass hierarchy has already been proposed in the same type of composite models [8], and it is based on the hierarchy between many energy scales in the model. A special feature of the mechanism proposed in this paper is its independence from the scale hierarchy in the model.

We conclude this paper by enumerating both the satisfactory and unsatisfactory points of the model. The satisfactory points of the model are as follows.

1. It is naturally understood why the top-quark mass is of the order of the weak scale and why the other quarks are much lighter than that scale.
2. The mass hierarchy among up-type quarks and the one between the down and strange quarks can be explained only by a parameter of the kinetic-term mixing ε .
3. The hierarchy of the compositeness scales in each generation can be naturally explained by considering the “unification” of confining forces at the Planck scale.
4. The representation of the fundamental particles is simple. The representation is vector-like under each factor of the gauge group, and there is no particle which belongs to the high-dimensional representation.

On the other hand the major problems of the model are as follows.

1. There are many assumptions on the dynamics; the spontaneous $U(1)_R$ symmetry breaking and the mass generation for X particle in the supersymmetry breaking sector, having the top-quark Yukawa coupling of the order of unity in the low energy limit, and the origin of the kinetic-term mixing.
2. The hierarchy among couplings in the tree-level superpotential.
3. The relatively light supersymmetric masses of the heavy Higgs fields may allow the radiative electroweak symmetry breaking in the first and second generations.
4. There is no symmetry which forbids proton decay. The difference between the baryon number and the lepton number is conserved, but the baryon number itself is not conserved. The model is safe against the experimental bound, since we are assuming no kinetic-term mixing among charged leptons and small couplings in the tree-level superpotential. (see also the discussion in Ref. [9]).

The mass hierarchy among the charged leptons and neutrinos is not explained in this model. But it is interesting that there is a relation between the smallness of neutrino masses and the long life time of proton.

We can discuss the non-trivial Cabibbo-Kobayashi-Maskawa mixing in this model. But it is premature, because there are many problems to solve. This model should be understood as a realization of the mechanism which is proposed in this paper.

TABLES

	$SU(2)_3$	$SU(3)_C$	$SU(2)_L$	$U(1)_Y$	$U(1)_{B-L}$
C_3	2	3	1	-1/3	-1/6
D_3	2	1	2	1/2	1/2
N_3	2	1	1	0	-1/2
$\bar{d}_3$	1	3*	1	1/3	-1/3
l_3	1	1	2	-1/2	-1
$\bar{\nu}_3$	1	1	1	0	1
$\bar{\Phi}_3$	1	3*	1	1/3	2/3
$\bar{H}_3$	1	1	2	-1/2	0

TABLE I. Particle contents of the third generation.

	$SU(2)_S$	$SU(2)_3$	$U(1)_R$	$U(1)_{B-L}$	$SU(2)_{global}$	$Sp(2)_{global}$	$U(1)_i$
$\tilde{Q}$	2	2	0	0	1		0
Q	2	1	0	0	2	4	0
$\tilde{Z}$	1	2 ^(*)	2	0	2 ^(*)		0
Z'	1	1	2	0	1	5	0
Z	1	1	2	0	1	1	0
X_1	1	2	1	-1/2	1	1	1
X_2	1	2	1	1/2	1	1	-1

TABLE II. Particle contents of the supersymmetry breaking sector. The index $i = 1, 2$ and 3 denotes the generation.

	$SU(2)_i$	$SU(3)_C$	$SU(2)_L$	$U(1)_Y$	$U(1)_{B-L}$	$U(1)_i$
C_i	2	3	1	-1/3	-1/6	0
D_i	2	1	2	1/2	1/2	0
N_i	2	1	1	0	-1/2	1
$\bar{d}_i$	1	3*	1	1/3	-1/3	1
l_i	1	1	2	-1/2	-1	1
$\bar{\nu}_i$	1	1	1	0	1	-1
$\bar{\Phi}_i$	1	3*	1	1/3	2/3	-1
$\bar{H}_i$	1	1	2	-1/2	0	-1

TABLE III. Particle contents of three generations. The index $i = 1, 2$ and 3 denotes the generation.

FIGURES

FIG. 1. Diagrams for the charm and down quark mass generation through the kinetic-term mixing and $B - L$ interactions.

FIG. 2. Running of hypercolor gauge couplings.

FIG. 3. The diagrams for the charm and up quarks mass generation. The solid and dashed line denote the fermion and boson, respectively.

FIG. 4. The diagrams for the strange and down quarks mass generation. The solid and dashed line denote the fermion and boson, respectively.
